

How to use the Logistics Estimation Tool

An estimation tool used by dispatch callers to be able to glance at, monitor, input driver positions on a map that covers the general routes.

User Interface

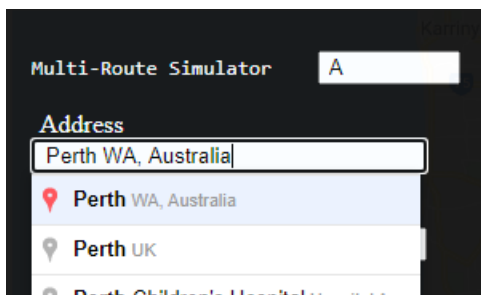

The screenshot shows the 'Multi-Route Simulator' interface. It features a dark background with white text. At the top left, the title 'Multi-Route Simulator' is displayed. To its right is a 'Route label...' input field. Below the title, there are two 'Address' input fields, each with a placeholder text 'Start typing here to add destination...'. To the right of these fields is a map showing a portion of a city with roads and landmarks. Below the address fields, there is a 'Departure Time' section with a time picker set to '08:00 AM' and a clock icon, and a digital clock showing '20:20:02'. A 'Calculate' button is positioned below the time section. At the bottom, the word 'Routes' is displayed.

There are 3 mandatory inputs to the tool: 2 addresses and a departure time. The route label is a optional input which will default to a numbering system starting at 0.

The departure time specifies the wall clock time that the simulation should initiate. If the departure time has passed the current time of the current local day, the simulation will start without delays. Otherwise, the simulation will hold the path until the specified departure time.

The Calculate button will submit the given addresses to Google and return a by-car route if one is available.

This screenshot shows the 'Multi-Route Simulator' interface with the first address input field filled with 'Perth WA, Australia'. Below the input field, a dropdown menu displays autocomplete suggestions: 'Perth WA, Australia' (with a red location pin icon), 'Perth UK' (with a grey location pin icon), and 'Perth Children's Hospital' (with a grey location pin icon). The 'Route label...' field at the top right now contains the letter 'A'. The 'Departure Time' section and the 'Calculate' button are also visible.

Each address input bar has autocomplete provided by Google. If every address is filled, a new address input bar will appear. It is necessary that only the final input bar is empty.

Address

Departure Time:

Routes

Perth WA, Australia 18:30 ⇒ Subiaco WA, Australia 18:39 ⇒ Nedlands WA, Australia 19:03 (0Hrs 33Mins - 8.9km) [18:30 → 19:03] {A}

After clicking the Calculate button on a valid request, the result will be displayed under the Routes heading and on the map.

Multiple routes can be independently added to the estimation tool and will operate completely independently according to their specified inputs.

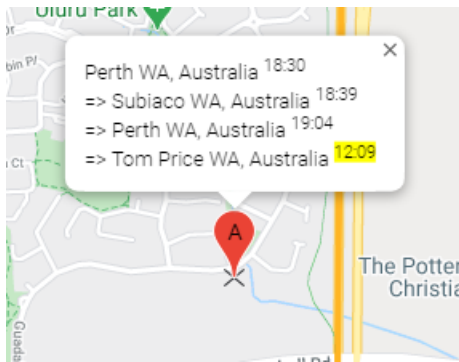

Each route in the route information panel has 4 buttons to manage the data and simulation.

- The left most vehicle button starts the simulation
- A pause button appears after clicking the start simulation button to pause simulation and allow for marker dragging
- The stop button removes the marker from simulation and allows for editing and removing
- The pencil button re-enters the data back into the input bars and removes it from the Routes information panel and the map.
- The bin button completely removes the route from the Routes information panel and the map.

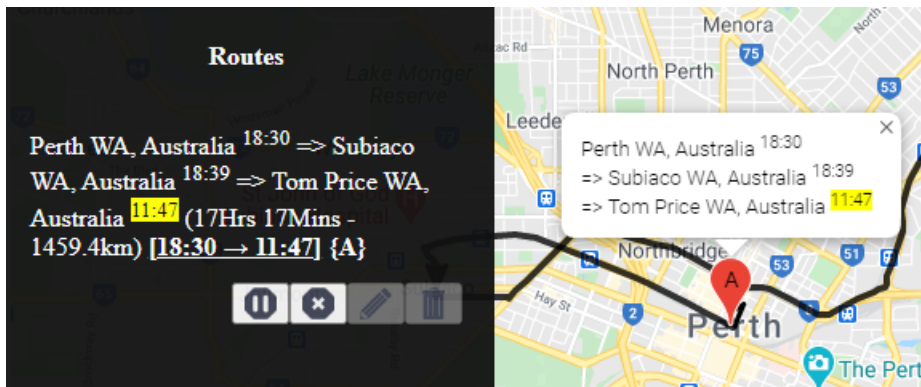

Clicking on a marker will reveal an Information Window containing a simplified view of the destinations and destination times.

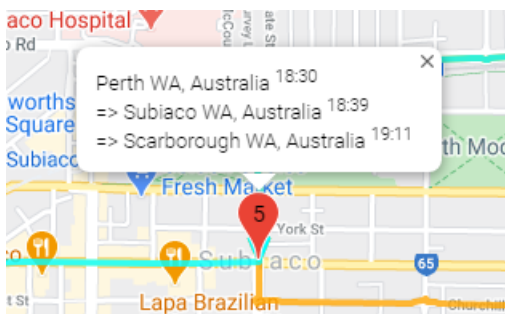

When the simulation is paused, the marker can be dragged. This is generally intended for more accurate positions if the simulation is incorrect. The dragged marker will snap to the closest point on the route when simulation is started again. Note: Generally if the route has a return path, keep left (Australia) will often result in the correct continuation of the path.

Timers

If any destinations are reached beyond the local day's following midnight, it will be highlighted. This is used to alert for over-night jobs.

By default, the simulating marker will stop at every waypoint for 15 minutes. It will also stop in the middle of travel after 5 hours from departure for 30 minutes.

All wall clock destination times include these delays.
